

# Long-term Conservation of Geometric Invariants by Newmark Beta methods

Numerical Computation Structured Projects

Hilary Term, 2018

# Introduction

# Geometric Numerical Integration

- Relatively young field - came into limelight around 40 years ago
- Study of numerical solutions to ordinary differential equations had begun in the late 19<sup>th</sup> Century
- The focus had been on quantity - making the solutions as accurate as possible
- Interest in computer simulations over a longer time frame raised an important question

# Geometric Numerical Integration

- Relatively young field - came into limelight around 40 years ago
- Study of numerical solutions to ordinary differential equations had begun in the late 19<sup>th</sup> Century
- The focus had been on quantity - making the solutions as accurate as possible
- Interest in computer simulations over a longer time frame raised an important question

What about the quality of solutions?

## Example: Lotka-Volterra Equations

$$\begin{aligned}\frac{du}{dt} &= u \cdot (1 - v), \\ \frac{dv}{dt} &= (u - 2) \cdot v,\end{aligned}$$

where  $u(t)$  is the population of the prey over time, and  $v(t)$  is that of the predator. Dividing the two equations, we get that

$$\left(1 - \frac{2}{u}\right) du = \left(\frac{1}{v} - 1\right) dv.$$

Integrating the two sides of the equation, we get that

$$I(u, v) = u - 2 \ln u + v - \ln v = \text{const}$$

## Example: Lotka-Volterra Equations

Defining  $a(u, v) := u \cdot (1 - v)$ , and  $b(u, v) := (u - 2) \cdot v$

- Explicit Euler Method

$$\begin{aligned}u_{n+1} &= u_n + h \cdot a(u_n, v_n), \\v_{n+1} &= v_n + h \cdot b(u_n, v_n).\end{aligned}$$

- Implicit Euler Method

$$\begin{aligned}u_{n+1} &= u_n + h \cdot a(u_{n+1}, v_{n+1}), \\v_{n+1} &= v_n + h \cdot b(u_{n+1}, v_{n+1}).\end{aligned}$$

- Symplectic Euler Method

$$\begin{aligned}u_{n+1} &= u_n + h \cdot a(u_{n+1}, v_n), \\v_{n+1} &= v_n + h \cdot b(u_{n+1}, v_n).\end{aligned}$$

# Example: Lotka-Volterra Equations

Initial Conditions:  $N = 1000$ ,  $h = 0.02$ ,  $(u_0, v_0) = (2, 4)$

## Newmark Beta methods

---

# Newmark Beta methods

$$\mathbf{v}_{i+1} = \mathbf{v}_i + h[(1 - \gamma) \mathbf{a}_i + \gamma \mathbf{a}_{i+1}],$$

$$\mathbf{x}_{i+1} = \mathbf{x}_i + h\mathbf{v}_i + \frac{h^2}{2} [(1 - 2\beta) \mathbf{a}_i + 2\beta \mathbf{a}_{i+1}],$$

where  $\gamma \in [0, 1]$  and  $\beta \in [0, \frac{1}{2}]$ .

- Implicit if  $\beta > 0$
- Explicit If  $\beta = 0$  and acceleration depends only on displacement
- Second order accurate  $\Leftrightarrow \gamma = \frac{1}{2}$
- Conditionally stable  $\Leftrightarrow 2\beta \geq \gamma \geq \frac{1}{2}$

# Computational Application of Newmark Beta methods

## Application of the General Procedure

In general unless  $\beta$  is 0 we may proceed with our calculation as follows:

- (1) Assume values of the acceleration of each mass at the end of the interval.
- (2) Compute the velocity and the displacement of each mass at the end of the interval from Eqs. (4) and (3), respectively. (Unless damping is present it is not necessary to compute the velocity at the end of the interval until step (5) is completed.)
- (3) For the computed displacements at the end of the interval compute the resisting forces  $R$  which are required to hold the structural framework in the deflected configuration.
- (4) From Eq. (1) and the applied loads and resisting forces at the end of the interval recompute the acceleration at the end of the interval.
- (5) Compare the derived acceleration with the assumed acceleration at the end of the interval. If these are the same the calculation is completed. If these are different, repeat the calculation with a different value of assumed acceleration. It will usually be best to use the derived value as the new acceleration for the end of the interval.

# Computational Application of Newmark Beta methods

$$\mathbf{v}_{i+1} = \mathbf{v}_i + h [(1 - \gamma) \mathbf{a}_i + \gamma \mathbf{a}_{i+1}(\mathbf{x}_{i+1})],$$

$$\mathbf{x}_{i+1} = \mathbf{x}_i + h\mathbf{v}_i + \frac{h^2}{2} [(1 - 2\beta) \mathbf{a}_i + 2\beta \mathbf{a}_{i+1}(\mathbf{x}_{i+1})].$$

.....

$$\tilde{\mathbf{F}}(\mathbf{x}_{i+1}) = \mathbf{x}_{i+1} - \mathbf{x}_i - h\mathbf{v}_i - \frac{h^2}{2} [(1 - 2\beta) \mathbf{a}_i + 2\beta \mathbf{a}_{i+1}(\mathbf{x}_{i+1})],$$

$$D_{\mathbf{x}_{i+1}} \tilde{\mathbf{F}}(\mathbf{x}_{i+1}) = \mathbf{I} - \beta h^2 \mathbf{J}_{\mathbf{a}_{i+1}},$$

$$\mathbf{x}_{i+1} = \mathbf{x}_i - D\tilde{\mathbf{F}}(\mathbf{x}_i)^{-1} \tilde{\mathbf{F}}(\mathbf{x}_i).$$

# Molecular Dynamics

---

# Hamiltonian System

We have to solve the Hamiltonian

$$H(p, q) = \frac{1}{2} \sum_{i=1}^N m_i^{-1} p_i^T p_i + \sum_{i=1}^{N-1} \sum_{j=i+1}^N V(\|q_i - q_j\|_2).$$

# Lennard-Jones Potential

$$V(\mathbf{r}_{ij}) = 4\epsilon \left[ \left( \frac{\sigma}{r_{ij}} \right)^{12} - \left( \frac{\sigma}{r_{ij}} \right)^6 \right],$$

where

$\mathbf{r}_{ij}$  is the displacement between the  $i^{th}$  and the  $j^{th}$  atoms

$$r_{ij} = \|\mathbf{r}_{ij}\|_2$$

$\epsilon$  is the potential well depth

$\sigma$  is the distance at which the potential between two atoms is 0

# Calculation of Forces

We have that force  $\mathbf{f}$  along the vector  $\mathbf{r}_{ij}$  is given by

$$\begin{aligned}\mathbf{f}(\mathbf{r}_{ij}) &= -\frac{dV}{d\mathbf{r}_{ij}} \\ &= 48 \cdot \varepsilon \cdot \sigma^6 \left[ \sigma^6 \left( \frac{1}{r_{ij}} \right)^{14} - \frac{1}{2} \left( \frac{1}{r_{ij}} \right)^8 \right] \mathbf{r}_{ij}\end{aligned}$$

Adding these terms up, the force exerted on particle  $i$ ,  $\mathbf{F}_i$  is given by

$$\mathbf{F}_i = \sum_{i \neq j} \mathbf{f}_{ij}.$$

# Simulation Details

- Initial Positions: cube of 864 particles at a density of  $1.374 \text{ g} \cdot \text{cm}^{-3}$

Figure: Face-centered cubic lattice of 864 particles at a density of  $1.374 \text{ g} \cdot \text{cm}^{-3}$

# Simulation Details

- Initial Velocities: Maxwellian distribution of velocities

$$f_{\mathbf{v}}(v_x, v_y, v_z) = \left( \frac{m}{2\pi k_B T} \right)^{\frac{3}{2}} \exp \left[ -\frac{m(v_x^2 + v_y^2 + v_z^2)}{2k_B T} \right].$$

$$\text{So, } v_x, v_y, v_z \sim \mathcal{N} \left( 0, \frac{k_B T}{m} \right)$$

# Simulation Details

- Equilibration

## Conservation of Geometric Invariants

---

## Time Reversibility

---

# Time Reversibility

## Theorem

*A Hamiltonian system is time reversible.*

## Proof.

We apply the transformation  $t \mapsto -t$ .

$$q \mapsto q = \tilde{q}, \quad p \mapsto -p = \tilde{p}.$$

Then

$$\begin{aligned} \ddot{q} &= \frac{d\tilde{q}}{d(-t)} = -\nabla_{\tilde{p}} H = \nabla_p H = \dot{q}, \\ \ddot{p} &= \frac{d\tilde{p}}{d(-t)} = -\nabla_{\tilde{q}} H = -\nabla_q H = \dot{p}. \quad \square \end{aligned}$$

# Time Reversibility

- A numerical one-step method  $\Phi_h : (\mathbf{x}_i, \mathbf{v}_i) \mapsto (\mathbf{x}_{i+1}, \mathbf{v}_{i+1})$  is time reversible if  $\Phi_h = \Phi_{-h}^{-1}$ .
- Informally, this means that if we exchange  $i \leftrightarrow i + 1$  and replace  $h$  by  $-h$  in our original method, then we should get the same method back.
- Any Newmark Beta method with  $\gamma = \frac{1}{2}$  is reversible.
- No other Newmark Beta method is reversible.
- However, rounding-off errors in practice mean that we may not get back the initial state of the system after reversing the velocities.

# Time Reversibility

**Figure:** Changes in position and velocities for  $\beta = 0.00$  and  $\gamma = 0.50$  after reversing 500 steps

# Time Reversibility

**Figure:** Changes in position and velocities for  $\beta = 0.00$  and  $\gamma = 0.75$  after reversing 500 steps

# Time Reversibility

**Figure:** Difference in behaviour of total energy for  $\beta = 0.00$  and  $\gamma = 0.75$  over different timesteps

# Time Reversibility

**Figure:** Changes in position and velocities for  $\beta = 0.25$  and  $\gamma = 0.50$  after reversing 125 steps

## Total Angular Momentum

---

# Total Angular Momentum

## Claim

Angular momentum,  $\mathbf{L} = \sum_{i=1}^N \mathbf{q}_i \times \mathbf{p}_i$ , is preserved  $\Leftrightarrow \beta = 0, \gamma = \frac{1}{2}$ .

## Proof.

$$\begin{aligned} \mathbf{L}_{i+1} - \mathbf{L}_i &= \sum_{k=1}^N (\mathbf{q}_{i+1})_k \times (\mathbf{p}_{i+1})_k - \sum_{k=1}^N (\mathbf{q}_i)_k \times (\mathbf{p}_i)_k \\ &= h^2 \left( \gamma - \frac{1}{2} \right) \sum_{k=1}^N (\mathbf{a}_i)_k \times (\mathbf{p}_i)_k \\ &\quad + h^2 \beta \sum_{k=1}^N (\mathbf{a}_{i+1})_k \times (\mathbf{p}_{i+1})_k - (\mathbf{a}_i)_k \times (\mathbf{p}_i)_k. \end{aligned}$$

So  $\mathbf{L}_{i+1} - \mathbf{L}_i = 0 \Leftrightarrow \beta = 0, \gamma = \frac{1}{2}$ .

# Total Angular Momentum

Iteration	x-component	y-component	z-component
10	493.28	-402.32	1407.30
20	-4.80	-10.18	914.24
30	320.20	-147.35	980.93
40	717.70	-181.21	704.27
50	594.66	152.47	507.19

**Table:** Total angular momentum of the system with  $\beta = 0, \gamma = \frac{1}{2}$  over the first 50 iterations

Total Energy

---

## Recap: Physical Interpretation of $\gamma$

- $\gamma$  plays the role of a damping factor in the energy of the system.
- The energy of the system is damped by a factor of  $\gamma - \frac{1}{2}$ .
- If  $\gamma > \frac{1}{2}$ , the energy is damped.
- If  $\gamma < \frac{1}{2}$ , the energy grows.

# Total Energy - Implicit Methods

We start by quoting Simo, Tarnow, and Wong:

*“What may seem surprising is that all of the implicit members of the Newmark family, perhaps the most widely used time-stepping algorithms in nonlinear structural dynamics, are not designed to conserve energy and also fail to conserve momentum.”*
